Study Objective: Mandibular advancement devices have been used to efficiently treat mild to moderate obstructive sleep apnea by effecting a forward positioning of the tongue-mandible complex and a resultant increase in oropharyngeal volume. These devices are essentially tooth anchored and hence, work well in dentate patients. However, it is difficult to anchor such devices in an edentate mouth. This clinical study presents a case series on use of complete dentures modified to function as mandibular advancement device.

Methods: Ten edentulous OSA patients (8 male and 2 female, aged 61 ± 4 years; BMI 22 ± 5; AHI 15-30) who volunteered and provided written informed consent were included in the study. All of them were provided with complete dentures, and after 1 month of comfortable wear and attaining optimum function, the prosthesis was modified to serve alternatively as a mandibular advancement device. Use of complete dentures as MAD was recorded separately. Five variables were assessed preoperatively and after 6 months of wearing the modified mandibular advancement device. The variables were: sleep efficiency, apnea-hypopnea index, oxygen desaturation events/h, mean \(O_2\) saturation, and snoring index. Overnight polysomnography was done to evaluate the sleep variables preoperatively and after 6 months of wearing the modified mandibular advancement device.

Results: A significant decrease in apnea-hypopnea index (AHI) from 22.5 preoperatively to 4.8 postoperatively (\(p = 0.005\)) and snoring index from 7.9 preoperatively to 2.1 postoperatively (\(p = 0.005\)) was observed after 6 months of use of the modified oral appliance. Sleep efficiency increased from 62.55% preoperatively to 73.20% postoperatively (\(p = 0.005\)).

Conclusions: The results indicate that within the limits of the present study, this specific MAD can be effective in reducing sleep apnea by lowering the AHI, reducing snoring and oxygen desaturation events/h and increasing sleep efficiency.

Keywords: mandibular advancement device, obstructive sleep apnea, complete edentulism

Obstructive sleep apnea (OSA) syndrome is a serious medical condition that affects substantial number of individuals. The worldwide OSA prevalence rates in adults ranges between 3.5% to 27%.1,2 In India, its prevalence ranges between 3% and 28% in men and 2.2% and 16% in women.3,4 It is characterized by a disruption of normal sleep architecture due to partial or complete obstruction of the respiratory airflow. Airflow obstruction leads to a reduction of blood oxygen saturation, also known as hypoxemia. This produces an arousal in an attempt to reopen the airway. Recurrent arousals disrupt the sleep architecture, diminish the quality of sleep, and cause excessive daytime somnolence. These features have a deleterious effect on the quality of life and state of health of affected individuals.5

Studies suggest that edentulism worsens sleep apnea.6 Loss of vertical dimension of occlusion causes reduction of the lower facial height and rotation of the mandible. Sleeping without dentures may be associated with a significant increase in the AHI.7 The lack of a vertical stop facilitates an overclosure of the maxillomandibular system and an upper airway collapse. Even in a patient using complete dentures, the vertical dimension of occlusion worsens continuously because of bone resorption.8

During the last two decades, there has been increased interest in oral appliance (OA) as a treatment modality for OSA. The OA is used during night; it protrudes the mandible and thereby opens the airway. The oral appliance is easy to use as it does not require electrical power and does not make any noise; crossover studies have shown that patients prefer OA therapy to CPAP, which leads to good compliance.

Oral appliances can either be prefabricated or custom made. Custom-made mandibular advancement devices (MADs) are fabricated on dental casts of the patient. All MADs have been developed for dentate patients in whom the remaining dentition provides anchorage and stability to the device. Only tongue retaining devices (TRD) have been recommended for edentate patients.9,10 Earlier clinical studies on the use of dentures for the treatment of OSA11-13 have not reported data on mandibular advancement. This clinical study presents a case series on use of complete dentures modified to function as MAD.

Methods

The present study was conducted in the Department of Prosthodontics, Saraswati Dental College & Hospital, Lucknow, in collaboration with Department of Pulmonary Medicine, King George’s Medical University, Lucknow. Prior approval of the Institutional ethical committee had been obtained.

Ten edentulous OSA patients (8 male, 2 female, age 61 ± 4 years; BMI 22 ± 5; AHI 15-30), who volunteered and provided written informed consent were included in the study. A provisional selection of patients was based on subjective evaluation of symptoms, according to the Epworth Sleepiness Scale and the
Berlin Questionnaire. Such patients were subjected to overnight polysomnography to confirm their actual status before being included as study subjects. Five variables were assessed preoperatively and after 6 months of wearing the modified MAD. These variables were: sleep efficiency, AHI, oxygen desaturation events/h, mean O₂ saturation, and snoring index.

For recording sleep efficiency, AHI, oxygen desaturation events/h, limb movement and mean O₂ saturation, overnight polysomnography was performed twice (preoperatively and after 6 months of wearing the appliance).

Overnight polysomnography sleep study (S-7000, Cogent technologies, EMBLA System Inc) included electroencephalograms (EEG); (C3-A2, C4-A1, O2-A1, O3-A2), bilateral electrooculogram (ROC, LOC), chin and leg electromyogram (EMG), nasal airflow, thoracic and abdominal movements, electrocardiogram (ECG), O₂ saturation measurement by finger pulse oximeter, and body position recorders. Apnea-hypopnea index (AHI) was calculated with the help of Somnologica Studio software. The apnea episodes were defined as complete cessation of airflow ≥ 10 s, and hypopnea was defined as ≥ 50% reduction in oronasal airflow accompanied by a reduction of ≥ 4% oxygen saturation calculated by pulse oximetry. AHI was determined by the frequency of these events per hour during sleep time based on the results of the overnight polysomnography. Recorded polysomnographic data were cross checked manually for scoring of sleep stages, apneas, and hypopnea events.

For grading of snoring intensity, the bed partner snoring evaluation index tool was used (Figure 1). As the sample size was small a nonparametric assessment plan was adopted. Data were analyzed using SPSS Version 15.0. Wilcoxon signed rank test was used to evaluate before-after changes. A p value < 0.05 indicated statistically significant difference.

Complete Denture Prosthesis Modified To Function as a Mandibular Advancement Device

Maxillary and mandibular complete dentures were fabricated by the conventional standard procedure. With the maxillary denture in the patient’s mouth, facebow records were taken and transferred onto the Hanau “wide vue” articulator. A 3-mm thick wax interocclusal record was made and maximum protrusive jaw movement was done, as dictated by the condylar guidance path. The mandibular denture was mounted on the articulator using the wax record. The wax record was removed and the centric lock of the articulator was fixed at 70% of maximum protrusion. Next, the heat cure soft liner (Permasoft) was added on the occlusal surface from the first premolar up to the second molar. The articulator was closed and the soft liner was allowed to set. The soft liner wafer was then cured, and thereafter the entire assembly (the maxillary and mandibular dentures and the soft liner wafer) was removed from the articulator. A hole was drilled at the first molar region on the intaglio surface of maxillary denture bilaterally, passing through the soft liner wafer up to the occlusal surface of mandibular denture, such that the two could be engaged securely. The soft liner wafer was fixed to the maxillary and mandibular denture using brass screws passing through the hole. This was done so that dentures could provide the function of mastication by removing the wafer during the daytime and then function as a mandibular advancement prosthesis by placing the wafer and tightening it with screws during sleep at night. The wafer engaged the posterior occlusion and created an interarch anterior space, which facilitated unobstructed inspiration even during sleep. The 3-piece modified mandibular advancement device (maxillary and mandibular dentures with soft liner wafer in between), was inserted and adjusted intraorally. The patient was provided with a brass mini-screwdriver and was instructed on how to screw the denture and soft liner wafer during night and to unscrew it during daytime (Figures 2-8).

RESULTS

A significant decrease in AHI from 22.5 preoperatively to 4.8 postoperatively (78.67%), snoring index (from 7.9 preoperatively to 2.1 postoperatively [73.42%]) and oxygen desaturation events/h (from 18.84 preoperatively to 5.04 postoperatively) was observed after 6 months of wearing the modified oral appliance. Sleep efficiency increased from 62.55% preoperatively to 73.20% postoperatively. However, there was no statistically significant improvement in mean O₂ saturation event (p value > 0.05; Table 1). For a mean change of 10.65 units with a pooled standard deviation of 6.49 units, the power of test was 100%.

DISCUSSION

The present study found the use of complete dentures with modifications to be an effective mandibular advancement device for the treatment of obstructive sleep apnea in a sample of edentulous patients. The MAD was retained by the edentulous arches and stabilized by screwing on the interocclusal wafer with the maxillary and the mandibular dentures, thus rendering the three as one composite unit. Placement of the wafer between the dentures increased the interarch distance with the maxillary and the mandibular dentures, thus favoring the reduction of apnea episodes.19

Recently, a few studies have shown that oral appliances could be used in partially and totally edentulous patients with OSA.20 Giannasi et al. applied an adjustable MAD on a maxillary edentulous patient with a dentate mandible.21 They reported a sharp decrease in AHI from 18.0 to 2.2/h. Nayar and Knox22 reported some advantages of an individually fabricated MAD in a totally edentulous patient with OSAS. They reported improvement of patient compliance based on subjective data (such as patient history) without polysomnography. Kurtulmus and Cotert fabricated a combination of TRD and MAD for a totally edentulous patient.23

The efficacy of MAD in the treatment of edentulous patients with OSA has been reported in previous studies. In a study by Arisaka et al. comprising 34 OSA patients (AHI ≥ 5), the mean AHI in patients sleeping with dentures was lower than that of those without dentures (13.3 ± 10.0 versus 17.7 ± 14.6, p = 0.022).13 The result showed that 70% of the individuals showed marked improvement in AHI after wearing dentures. However, this study did not show the effect of denture advancement on sleep variables.

Erovigni et al. showed by cephalometric evaluation that wearing denture induces modifications in the position of the tongue, of the jaw, and of the pharyngeal airway space that can favor the reduction of apnea episodes.19

CONCLUSION

The results indicate that within the limits of the present study, this specific MAD is effective in reducing sleep apnea by lowering the AHI and reducing snoring and oxygen desaturation events/h in a significant way along with improvement in sleep efficiency. The MAD has been well tolerated by all patients.
